# 16.00 Introduction to Aerospace and Design 

Problem Set \#3

## AIRCRAFT PERFORMANCE FLIGHT SIMULATION LAB Solution

I collected flight data at 10 different conditions, and also flew from $10,000 \mathrm{ft}$ to $9,000 \mathrm{ft}$ to get more time to fly stably and more accurately measure vertical speed.

Data are shown in the table below.
Indicated airspeed computed directly from the airspeed indicator and converted to $\mathrm{ft} / \mathrm{s}$
True airspeed $=1.154 x$ (indicated airspeed) as per Problem Set \#3 handout
Vertical speed computed from the Flight Analysis tool, converted to ft/s
Flight path angle computed from $\gamma=\sin ^{-1}\left(\frac{\dot{\mathrm{~h}}}{\mathrm{v}}\right)$
Lift computed from $\mathrm{L}=\mathrm{W} \cos (\gamma)$
L/D computed from $\mathrm{L} / \mathrm{D}=\cot (\gamma)$
$\mathrm{C}_{\mathrm{L}}$ computed from $C_{L}=\frac{L}{1 / 2 \rho v^{2} S}$
$\mathrm{C}_{\mathrm{D}}$ computed from $C_{D}=C_{L} \frac{D}{L}$

| Flight <br> Condition | indicated <br> airspeed (ft/s) | true <br> airspeed (ft/s) | vertical <br> speed (ft/s) | flight path <br> angle (deg) | Lift (N) | L/D | Cl | Cd |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 72.62 | 83.81 | 2.31 | 1.58 | 849.68 | 36.30 | 0.76 | 0.02 |
| 2 | 79.38 | 91.60 | 2.45 | 1.53 | 849.70 | 37.34 | 0.63 | 0.02 |
| 3 | 87.82 | 101.35 | 2.78 | 1.57 | 849.68 | 36.48 | 0.52 | 0.01 |
| 4 | 96.27 | 111.09 | 3.19 | 1.65 | 849.65 | 34.76 | 0.43 | 0.01 |
| 5 | 103.02 | 118.89 | 3.73 | 1.80 | 849.58 | 31.89 | 0.38 | 0.01 |
| 6 | 113.16 | 130.58 | 4.61 | 2.02 | 849.47 | 28.29 | 0.31 | 0.01 |
| 7 | 131.73 | 152.02 | 6.54 | 2.47 | 849.21 | 23.21 | 0.23 | 0.01 |
| 8 | 148.62 | 171.51 | 9.35 | 3.12 | 848.74 | 18.32 | 0.18 | 0.01 |
| 9 | 172.27 | 198.80 | 14.17 | 4.09 | 847.84 | 14.00 | 0.13 | 0.01 |
| 10 | 209.42 | 241.67 | 25.24 | 6.00 | 845.35 | 9.52 | 0.09 | 0.01 |

From the data above, the aircraft should fly at approximately $84 \mathrm{ft} / \mathrm{s}$ true airspeed (or 43 kt indicated) to maximize time aloft (minimum sink rate).

The maximum L/D occurs at a true airspeed of $92 \mathrm{ft} / \mathrm{s}$ ( 47 kt indicated).

The plot above shows the data from the flight test, along with a parabolic curve fit with $\mathrm{C}_{\mathrm{D} 0}=0.009$ and efficiency $e=0.88$.

$$
\left(\frac{L}{D}\right)_{\text {max }}=\frac{1}{2} \sqrt{\frac{\pi e A R}{C_{D_{\mathrm{D}}}}}
$$

Theory predicts $\quad=37.2, \quad$ Observed maximum $L / D=37.3$

Theory predicts

$$
v_{\max _{\perp / D}}=\sqrt{\frac{2 W}{\rho S \sqrt{C_{D_{\mathrm{D}}} \pi e A R}}}=88.9 \mathrm{ft} / \mathrm{s}, \quad \text { Observed } \mathrm{v}_{\max L / D}=92 \mathrm{ft} / \mathrm{s}
$$

Errors between theory and observation are due to:

- inaccurate dynamic model in the flight simulator, especially close to stall - inaccurate data recording or non-steady flight during the flight test
- inaccuracies in the curve fit in the $\mathrm{C}_{\mathrm{D}}$ vs. $\mathrm{C}_{\mathrm{L}}$ drag polar to predict $\mathrm{C}_{\mathrm{D} 0}$ and $e$.
