With $\imath \equiv \sqrt{-1}$, the complex numbers can be defined as the space of numbers spanned by the vectors:

$$
\begin{equation*}
\binom{1}{0} \text { and }\binom{0}{2} \tag{8-1}
\end{equation*}
$$

so that any complex number can be written as

$$
\begin{equation*}
z=x\binom{1}{0}+y\binom{0}{\imath} \tag{8-2}
\end{equation*}
$$

or just simply as

$$
\begin{equation*}
z=x+i y \tag{8-3}
\end{equation*}
$$

where $x$ and $y$ are real numbers. $\operatorname{Re} z \equiv x$ and $\operatorname{Im} z \equiv y$.

## © Complex Plane and Complex Conjugates

Because the complex basis can be written in terms of the vectors in Equation 8-1, it is natural to plot complex numbers in two dimensions - typically these two dimensions are the "complex plane" with $(0, \imath)$ associated with the $y$-axis and $(1,0)$ associated with the $x$-axis.

The reflection of a complex number across the real axis is a useful operation. The image of a reflection across the real axis has some useful qualities and is given a special name - "the complex conjugate."

Figure 8-1: Plotting the complex number $z$ in the complex plane: The complex conjugate $(\bar{z})$ is a reflection across the real axis; the minus $(-z)$ operation is an inversion through the origin; therefore $-(\bar{z})=(-z)$ is equivalent to either a reflection across the imaginary axis or an inversion followed by a reflection across the real axis.
The real part of a complex number is the projection of the displacement in the real direction and also the average of the complex number and its conjugate: $\operatorname{Re} z=(z+\bar{z}) / 2$. The imaginary part is the displacement projected onto the imaginary axis, or the complex average of the complex number and its reflection across the imaginary axis: $\operatorname{Im} z=$ $(z-\bar{z}) /(2 \imath)$.

## Polar Form of Complex Numbers

There are physical situations in which a transformation from Cartesian $(x, y)$ coordinates to polar (or cylindrical) coordinates $(r, \theta)$ simplifies the algebra that is used to describe the physical problem.

An equivalent coordinate transformation for complex numbers, $z=x+\imath y$, has an analogous simplifying effect for multiplicative operations on complex numbers. It has been demonstrated how the complex conjugate, $\bar{z}$, is related to a reflection-multiplication is related to a counterclockwise rotation in the complex plane. Counter-clockwise rotation corresponds to increasing $\theta$.

The transformations are:

$$
\begin{align*}
& (x, y) \rightarrow(r, \theta)\left\{\begin{array}{l}
x=r \cos \theta \\
y=r \sin \theta
\end{array}\right. \\
& (r, \theta) \rightarrow(x, y)\left\{\begin{array}{l}
r=\sqrt{x^{2}+y^{2}} \\
\theta=\arctan \frac{y}{x}
\end{array}\right. \tag{8-4}
\end{align*}
$$

where $\arctan \in(-\pi, \pi]$.

$\qquad$

DeMoivre's formula:

$$
\begin{gather*}
z^{n}=r^{n}(\cos n \theta+\imath \sin n \theta)  \tag{8-5}\\
\sqrt[n]{z}=\sqrt[n]{z}\left(\cos \frac{\theta+2 k \pi}{n}+\imath \sin \frac{\theta+2 k \pi}{n}\right) \tag{8-6}
\end{gather*}
$$

Exponentiation and Relations to Trignometric Functions
Exponentiation of a complex number is defined by:

$$
\begin{equation*}
e^{z}=e^{x+i y}=e^{x}(\cos y+\imath \sin y) \tag{8-7}
\end{equation*}
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Exponentiation of a purely imaginary number advances the angle by rotation:

$$
\begin{equation*}
e^{\imath y}=\cos y+\imath \sin y \tag{8-8}
\end{equation*}
$$

combining Eq. 8-8 with Eq. 8-7 gives the particularly useful form:

$$
\begin{equation*}
z=x+\imath y=r e^{\imath \theta} \tag{8-9}
\end{equation*}
$$

and the useful relations (that can be obtained simply by considering the geometry of the complex plane)

$$
\begin{equation*}
e^{2 \pi \imath}=1 \quad e^{\pi \imath}=-1 \quad e^{-\pi \imath}=-1 \quad e^{\frac{\pi}{2} \imath}=\imath \quad e^{-\frac{\pi}{2} \imath}=-\imath \tag{8-10}
\end{equation*}
$$

Judicious subtraction of powers in Eq. 8-8 and generalization gives the following useful relations for trigonometric functions:

$$
\begin{align*}
\cos z=\frac{e^{\imath z}+e^{-\imath z}}{2} & \sin z=\frac{e^{\imath z}-e^{-i z}}{2 \imath} \\
\cosh z=\frac{e^{z}+e^{-z}}{2} & \sinh z=\frac{e^{z}-e^{-z}}{2}  \tag{8-11}\\
\cos z=\cosh \imath z & \imath \sin z=\sinh \imath z \\
\cos \imath z=\cosh z & \sin \imath z=\imath \sinh z
\end{align*}
$$
