## 1 Gibbons 4.1 (p.245)

### 1.1 Game A

The normal form representation of this game is the following:

|  | $L^{\prime}$ | $R^{\prime}$ |
| :--- | :--- | :--- |
| $L$ | $(4,1)$ | $(0,0)$ |
| $M$ | $(3,0)$ | $(0,1)$ |
| $R$ | $(2,2)$ | $(2,2)$ |

The pure-strategy Nash Equilibria are $\left(L, L^{\prime}\right)$ and $\left(R, R^{\prime}\right)$. Since there are no proper subgames, these are also subgame perfect.

Let us now find conditions on $p$ such that $\left(L, L^{\prime}\right)$ and $\left(R, R^{\prime}\right)$ are perfect Bayesian equilibria.

## Requirement 1

Player 2 has belief that player 1 has played $L$ with probability $p$ and $M$ with probability $1-p$

Requirement 2
Given $p$, player 2's expected payoff from playing $L^{\prime}$ and $R^{\prime}$ are
$E\left(L^{\prime}\right)=p ; \quad E\left(R^{\prime}\right)=1-p$
Thus, it is sequentially rational for player 2 to choose $L^{\prime}$ if and only if $p \epsilon[1 / 2,1]$ and $R^{\prime}$ if and only if $p \epsilon[0,1 / 2]$.

Given player 2's belief, player 1's strategy should also be sequentially rational. If player 2 chooses $L^{\prime}$, player 1 should choose $L$. If player 2 chooses $R^{\prime}$, player 1 should choose $R$.

## Requirement 3

Consider the NE ( $L, L^{\prime}$ ). Player 2 gets to play on the equilibrium path. Thus, player 2's belief $p$ must be 1 . So ( $L, L^{\prime}, p=1$ ) represents a pbe.

Consider the NE $\left(R, R^{\prime}\right)$. Player 2 does not have to play on the equilibrium path. Requirement 3 places no restrictions on $p$

Requirement 4
( $R, R^{\prime}$ ) is off the equilibrium path. Requirement 4 does not impose any restriction on $p$.

To sum up, we have the following two perfect Bayesian equilibria:
$\left(L, L^{\prime}, p=1\right),\left(R, R^{\prime}, p \epsilon[0,1 / 2]\right)$

### 1.2 Game B

The normal form representation of this game is the following:

|  | $L^{\prime}$ | $M^{\prime}$ | $R^{\prime}$ |
| :--- | :--- | :--- | :--- |
| $L$ | $(1,3)$ | $(1,2)$ | $(4,0)$ |
| $M$ | $(4,0)$ | $(0,2)$ | $(3,3)$ |
| $R$ | $(2,4)$ | $(2,4)$ | $(2,4)$ |

The only pure-strategy Nash Equilibria is $\left(R, M^{\prime}\right)$. Let us now find conditions on $p$ such that this equilibrium is perfect Bayesian.

## Requirement 1

Player 2 has belief that player 1 has played $L$ with probability $p$ and $M$ with probability $1-p$

## Requirement 2

Given $p$, player 2's expected payoff from playing $L^{\prime}, M^{\prime}$ and $R^{\prime}$ are
$E\left(L^{\prime}\right)=3 p ; \quad E\left(M^{\prime}\right)=2 ; \quad E\left(R^{\prime}\right)=3(1-p)$
When is it sequentially rational for player 2 to play $M^{\prime} ? M^{\prime}$ brings a higher expected payoff than $L^{\prime}$ if and only if $p \epsilon[0,2 / 3]$; it brings a higher expected payoff than $R^{\prime}$ if and only if $p \epsilon[1 / 3,1]$. The intersection of these two conditions is $p \epsilon[1 / 3,2 / 3]$.

Given player 2's belief, player 1's strategy should also be sequentially rational. If player 2 chooses $M^{\prime}$, player 1 should choose $R$.

## Requirement 3

Player 2 does not have to play on the equilibrium path. Requirement 3 places no restrictions on $p$.

## Requirement 4

( $R, M^{\prime}$ ) is off the equilibrium path. Requirement 4, by itself, does not impose any restriction on $p$. We only require that player 2's belief makes $\left(R, M^{\prime}\right)$ the optimal strategy for both players. From requirement 2, we have that $\left(R, M^{\prime}, p \epsilon[1 / 3,2 / 3]\right)$ is a pure-strategy perfect Bayesian equilibrium.
